ISO 10816-3:2009 gives criteria for assessing vibration measurements when made in situ. The criteria specified apply to machine sets having a power above 15 kW and operating speeds between 120 r/min and 15 000 r/min.

ISO 10816-3 was prepared by Technical Committee ISO/TC 108, Mechanical vibration, shock and condition monitoring, Subcommittee SC 2, Measurement and evaluation of mechanical vibration and shock as applied to machines, vehicles and structures. This second edition cancels and replaces the first edition (ISO 10816-3:1998).

ISO 10816 establishes the general conditions and procedures for measurement and evaluation of vibrations from the non-rotating parts of machines. Standards provide guidance for machines operating in the 10 to 200 Hz (600 to 12,000 RPM) frequency range.

Wind turbines are, however, expressly excluded from the scope of ISO 10816-3. The criteria laid down in the other parts of ISO 10816 would, in principle, be applicable to wind turbine components. However, these criteria apply only to vibration generated within the machine set itself, and thus, affect its components directly.

The ISO 10816-3 method is generally considered the safest method for taking “overall” measurements because it is less likely to result in an inadvertent exclude signal. Fortunately, the ISO also recognizes that 10816-3 does not cover all possible machinery fault frequencies.

Taking Accurate Vibration Measurements - Efficient Plant

As per ISO 10816 class 3, this machine should be stopped for maintenance when the velocity readings are >11.2 mm/sec. but we ran this machine with confidence more than a year based on envelope readings. As the envelope overall readings are <5 g. Conclusion: This type of scenario is expected in any plant.

I don't know of a standard called "10816". There are six parts...each with its own sub-part. Some of us have cited "10816-1". ISO "10816-3" is a more specific sub-part...and, I believe, more accurate for my purpose of measuring machine casing measurements.
